# Advanced Network Communications H - Assessed Coursework Network Description & Walkthrough

Name: Dominic Houston-Watt Matric: 2253422h

This file will cover the structure of network description files, provide diagrammatic versions of the provided network description files and give a runthrough of using the application to simulate the provided networks.

**Note:** To run your own network, follow the file structure below in a .txt file and place the file in the same directory as the runnable jar file.

#### File structure

Provided in the submission documents are 2 example networks. When the application is run, network1.txt is preloaded, however you can change what network file is loaded by using the load function in the application. The structure of the network description files are as follows

LINE 1 - Number of nodes in the network

LINES 2->n - Bidirectional edges in the network, written as node1\_label,
nodel2\_label, cost

This structure should be used if the user is wishing to simulate their own network, with a network description file.

## **Diagrams**

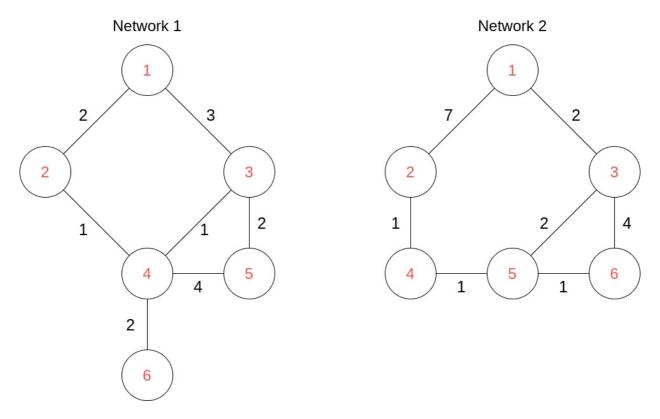

Fig 1: Diagrammic representations of the provided networks, with Nodes and links identified by labels and costs

### Walkthrough

This section will give a brief runthrough to show the evolution of the distance vector table and network simulation for the networks provided.

#### Network 1

Upon running the application, network 1 is pre loaded. First, printnet is used to see the initial distance vector table

Fig 2: printnet command output in the application

You can see that prior to calculation of distances, nodes that don't know the location of others in the DVT have a total cost of 999 and an outgoing node of null. For example, node 2 does not directly connect to node 3, so the cost is set to 999.

#### **Computing the DVT**

Next, compute can be run to perform the exchanges for the nodes, providing the number of iterations the user wants to perform (each iteration is when the nodes perform the exchanges)

```
Improved route identified from 6 to 2
         New Outgoing Node: 4
         New Cost: 3
Improved route identified from 6 to 3
         New Outgoing Node: 4
         New Cost: 3
Improved route identified from 6 to 1
         New Outgoing Node: 4
         New Cost: 5
Improved route identified from 6 to 5
         New Outgoing Node: 4
         New Cost: 5
Calculating...
Improved route identified from 1 to 6
         New Outgoing Node: 2
         New Cost: 5
Improved route identified from 2 to 5
         New Outgoing Node: 4
         New Cost: 4
################################## Iteration: 3

New Network DVT
Source || (Destination Node, Cost, Outgoing Node)
             (2,2,2), (3,3,3), (1,0,null), (5,5,3), (6,5,2), (4,3,2), (2,0,null), (3,2,4), (1,2,1), (5,4,4), (6,3,4), (4,1,4), (2,2,4), (3,0,null), (1,3,1), (5,2,5), (6,3,4), (4,1,4), (2,1,2), (3,1,3), (1,3,2), (5,3,3), (6,2,6), (4,0,null), (2,4,3), (3,2,3), (1,5,3), (5,0,null), (6,5,3), (4,3,3), (2,3,4), (3,3,4), (1,5,4), (5,5,4), (6,0,null), (4,2,4),
123456
```

Fig 3: Output from the compute command, showing the progression of route calculation

When calculations are performed, by using the Bellman-Ford algorithm, if a better route from a source to a destination is found the new cost and outgoing node are printed, as the iterations continue you can see that less paths are being identified, as the network comes closer to stabalisation.

The networks DVT (showing the DVT for every node in the network) is printed after the iterations have completed.

#### **Updating Links Between Nodes**

If the user wishes to update a node, say changing the cost from node 2 to node 4, the update command can be called. The allows the user to enter a new cost associated with the link, however after this the DVT for all nodes now needs to be recalculated incase of any better routes now being available. In the screenshots, the cost between nodes 2 and 4 are changed to a value of 13.

```
Enter a new command:
update
Please enter source node:
Node 2's neighbours: [1, 4]
Please enter neighbour link to change:
> 13
Neighbour link updated!
Enter a new command:
compute
Please enter the number of iterations you want to perform:
Initial Network DVT

```

Fig 4: update command being used. Highlighted entries in the DVT show the changes made once links were updated and routes were recalculated

#### Network 2

The same process performed on network 1 was performed on network 2. For this example, we can see how the use of the split horizon functionality changes how routes are calculated. Network 2 is loaded into the program using the load function, then printnet is run to display the network DVT.

Fig 5: printnet command output in the application

#### **Computing the DVT**

For this first pass, we can see how the routes are calculated with splithorizon being **disabled**.

```
Enter a new command:
compute
Please enter the number of iterations you want to perform:

```

Fig 6: Output from the compute command, without split horizon

#### **Enabling Split Horizon**

Now we can see how the routes are updated without split horizon capability, we enable it by using the toggle command.

```
Enter a new command:
toggle
Split Horizon Enabled: true
Enter a new command:
```

Fig 7: Enabling split horizon capability using the toggle command

Once split horizon is enabled, the calculate command is run to compute the DVTs of all nodes.

```
